Preventing Dog Obesity

Drs. Foster & Smith Educational Staff

Preventing your dog from becoming overweight is easier than taking off the excess weight once it is there. To prevent excess weight, we must feed our dogs according to their activity level and age. In general, younger dogs will need more calories per pound of body weight than older dogs whose metabolisms have slowed. To maintain optimum weight we need to:

Provide exercise

Exercise has many benefits. It not only helps to burn calories but it also:

- Strengthens respiratory and circulatory systems
- Helps get oxygen to tissue cells
- Keeps muscles toned and joints flexible
- Releases energy, relieves boredom, and keeps mind active
- Aids in digestion

Choose the correct type and amount of food

Dogs need different types and amounts of food during their life stages. Younger animals require more energy, protein, and minerals than older dogs. Active field trial dogs, and dogs who are outside in cooler weather would also have greater energy needs. Pregnant or nursing dogs require increased protein, minerals, and energy. 'Couch potato' dogs, however, have much lower energy needs. Older dogs, even if they remain active, may require fewer calories than when they were younger.

Some dogs regulate their intake well, others eat anything in sight. In general, it is best to provide food as 'meals' rather than having a food bowl filled with food available at all times (free choice, ad. lib.). This way it is easier to monitor intake and food will not become stale. In a multiple pet household, providing food as meals also helps to ensure the pet is eating the food appropriate for him.

Regularly monitor the dog's weight

It is easy for us to put on a couple of pounds and not notice it until we try wearing something we have not worn for a while. It is even harder to notice small weight gains in dogs. By routinely weighing your dog (at the same time of day, on the same scale), you will be able to notice a slight weight increase (or decrease) before it becomes a serious problem.

Regulate the weight of young dogs

Dogs who are overweight while growing have a greater risk of becoming overweight as adults. We need to make sure growing animals have adequate nutrition, but we do not want to feed too much. In addition to contributing to weight problems as the animal ages, excess weight when young can contribute to other problems such as joint disease.

Limit or eliminate treats and table scraps

The extra calories and decreased nutritional value of treats

and table scraps are often the biggest offenders when it comes to weight control. Treats are generally better than table scraps, and have their use, as when training dogs to 'come.' But giving too many treats can have serious consequences. Most dogs, when it comes right down to it, would rather have your attention than a treat. Spending extra time playing or grooming your dog will probably give you both much more satisfaction than the treat, which is gobbled up in three seconds and then forgotten.

older.

Treat any contributing factors or diseases

Although most weight gain in dogs is simply due to feeding too much or exercising too little, there are medical conditions which can contribute to obesity. Many of these conditions can be treated. If your dog has an unexplained increase in appetite or weight, have your dog examined by your veterinarian to be sure there is not a disease process causing the problem.
